Pooled effect size

- Number of studies = 273
- estimate = 0.1071, with 95% CI [0.087, 0.127]. However, this Fisher's z, so, we need to transform it back to Pearson r for interpretation

```
# Transform from z to r and see if the values you obtain make sense:
predict(meta2, digits=3, transf=transf.ztor)
```

```
## pred ci.lb ci.ub pi.lb pi.ub
## 0.107 0.084 0.130 -0.212 0.406
```

- estimate = 0.107, with 95% CI [0.084, 0.130]
- The prediction interval ranges is r = [-0.212, 0.406]. This means that it is possible that some future studies will find a negative correlation between mindset and academic achievement based on the present evidence. But the interval spans also over to a substantial positive effect.
- I will continue the analyses using meta1

Analysis of between-studies heterogeneity

• Cochrane's Q: If there was no heterogeneity this statistics should be distributed as a χ^2 distribution with 272 degrees of freedom. In our meta-analysis Q=8958.24 with p < .0001. We reject the null hypothesis of homogeneity. There is evidence for heterogeneity.

```
# Obtain confidence interval for tau 2, I2, H
# Interval for tau 2 is obtained iteratively either via the Q-profile method or via the generalized Q-s
# The square root of the inter- val bounds is also returned for easier interpretation.
# Confidence intervals for I2 and H2 are also provided (Higgins & Thompson, 2002). Since I2 and H2 are
confint.rma.uni(meta1, digits = 3)
```

```
## ## estimate ci.lb ci.ub

## tau^2 0.019 0.016 0.028

## tau 0.137 0.128 0.169

## I^2(%) 95.677 95.077 97.103

## H^2 23.132 20.312 34.523
```

- $I^2 = 95.68 (95\%\text{CI:}95.08 97.10\%)$, meaning that about 96% of the variability in effect sizes is due between-study heterogeneity. This can be considered substantial heterogeneity (according to Thompson's rule of thumb).
- H² is 23.13. Values greater than 1 indicate heterogeneity.
- τ^2 , the between-study variance, is 0.0187 with 95% confidence interval [0.016, 0.0284], which does not include zero. Indicates heterogeneity. The confidence interval for τ^2 was calculated based on the Q-profile method or the generalized Q-statistic method.
- τ , is the 'standard deviation of the true effect size and [...] it tells us something about the range of the true effect sizes. The true effect sizes have an estimated standard deviation of SD=0.1369 expressed on the scale of (Question: Pearson correlation or Fisher's Z?)

Forest plot

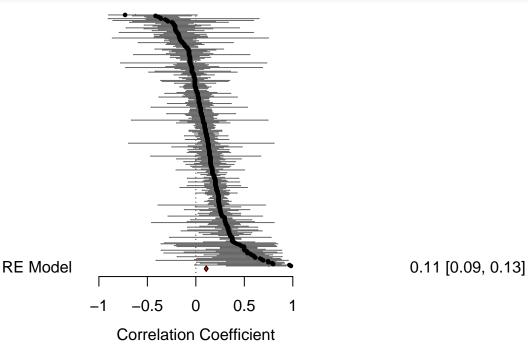

pdf ## 2

Notes:

 \bullet Many of the more precise studies (smaller confidence interval), have an average correlation between -0.03 and 0.24

Subgroup analysis

Sisks et al. (2018) found as **significant** moderators:

- Student factors:
 - Developmental stage of the student: children, adolescents, adults
- Developmental stage as a moderator of mind-set on GPA

Sisks et al. (2018) found as **non- significant** moderators:

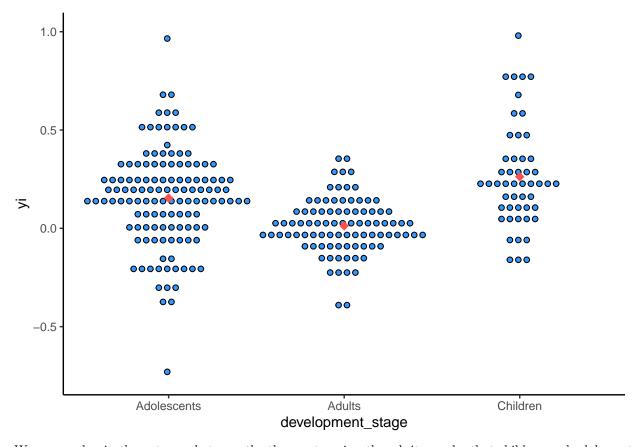

- Student factors:
 - Academic risk status: low-risk, moderately at risk, highly at-risk students
 - Socioeconomic status
- Academic achievement measure: Course exam, Course grade, GPA, Standardized test

Developmental stage

```
# Prepare dataset
levels(df3$development_stage)
## [1] "Wide Range" "Adolescents" "Adults"
                                                  "Children"
# Subset to exclude "Wide Range"
df3 develop <- filter(df3,
                      (development stage == "Adolescents") |
                        (development_stage == "Adults") |
                        (development_stage == "Children"))
# Adjust labels

  theme_classic()
```

```
## Warning: `fun.y` is deprecated. Use `fun` instead.
```

Bin width defaults to 1/30 of the range of the data. Pick better value with `binwidth`.

We see overlap in the outcome between the three categories, though it may be that children and adolescents show a higher effect than adults.

The range of values is larger for a dolescents and children compared to adults. Probably this would call for estimating different $\tan^2 2$ for each group

Next, I a weighted ANOVA. There are two options:

- common τ^2 :
- different τ^2

```

## Regression Test for Funnel Plot Asymmetry
##
## Model: weighted regression with multiplicative dispersion
## Predictor: standard error
##
## Test for Funnel Plot Asymmetry: t = -9.1604, df = 271, p < .0001
## Limit Estimate (as sei -> 0): b = 0.3149 (CI: 0.2975, 0.3323)
```

We cannot reject the null hypothesis that the intercept is equal to zero. Therefore we do not have evidence for funnel plot asymmetry. ("When there is no publication bias, the expected z score should be scattered around zero. No publication bias means means that the precision is not related to the effect size reported (beta1=0)).

    0
```

Chen, 2015 pg. 92: "I2 can be interpreted as the proportion of the total variation of the effect size that is due to the between-study heterogeneity"

- 4.17 % of the total variance can be attributed to within-study sampling variance (level-1)
- 75.43~% of the total variance can be attributed to within study variance (differences between effect sizes within studies)
- 20.4 % of the total variance can be attributed to differences between studies at level 3.

Conclusion: A lot of the variance is within-studies

Trim and Fill method

To perform the Trim and Fill, instead of ignoring dependence, like it was previously done, I can either sample one effect size per group or aggregate.

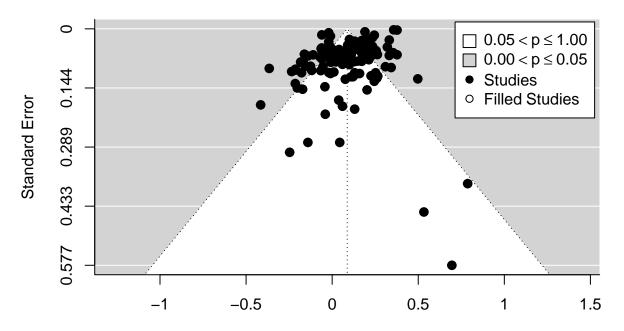

Here I create a new dataset where I aggregate the effect sizes

```
# Create dataset with aggregated effect sizes
# My code
# df4_aggregated<-
# df3 %>%
# group_by(study_id) %>%
\# summarise(new_n = sum(n),
            sum_yi = sum(yi),
#
            sum_vi = sum(vi),
#
            new_yi = (1/new_n)*sum_yi,
#
            new_vi = (1/new_n)*sum_vi)
# Reference: Rodgers RealData-Lehtonen-FinalTables.R, line 75
# df4_comparison <-
# df3 %>%
# group_by(study_id) %>%
# summarise_at(vars(yi, vi), mean)
# Fit a new model
\# meta3_aggreagated <- rma (yi = new_yi,
                            vi = new_vi,
#
                            measure = 'ZCOR',
#
                            data = df4\_aggregated,
                            method = 'REML')
# summary(meta3_aggreagated, digits = 3)
# Do trim and fill
```

Here I create a new dataset where I sample the effect sizes

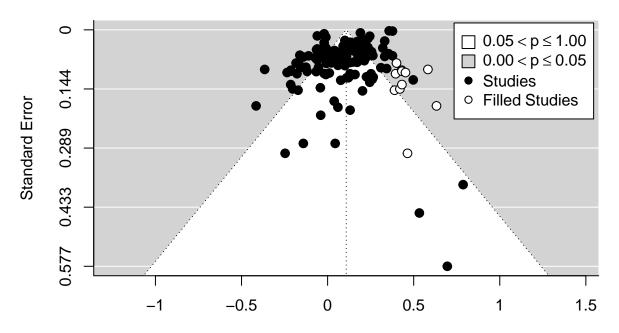

Random-Effects Model (k = 129; tau^2 estimator: REML)
